ABSTRACT

This report presents a statistical portrait of the social and economic characteristics, primarily during the 1970s, of persons 65-years old and over. Most of the estimates in this report are based on data from the Current Population Survey of the Bureau of the Census and from the Decennial Censuses of Population and Housing, particularly the 1970 census. Other data are provided by various governmental agencies. The sample population extends over 461 areas comprising 923 counties and independent cities in each of the 50 states and the District of Columbia. Data are included on family, material status, and fertility; institutional population; nativity and parentage; mobility and residence; education, vocational training, and literacy; voting; veterans; labor force participation, employment status, and occupation and industry; income and earnings; low-income status of persons and families; housing; health and health services; and crime victimization. Appendixes include reliability tables of the estimates. (Author/RM)

PREFACE

This report was prepared by Elmore J. Seraile, Ethnic Origins Statistics Staff, Population Division. General direction was provided by Charles E. Johnson, Jr., Assistant Chief, Population Division, and Paul C. Glick, Senior Demographer, Population Division. Statistical assistance was provided by Nancy L. Swann, and clerical assistance by Annise L. Chapmon and Angela M. Britt. Editorial assistance was provided by Vivian J. Brown and Karen M. Mills. Sampling review of the report was conducted by Paul H. Tomlin and George F. Train of the Statistical Methods Division.

Appreciation is also expressed to the other government agencies which made data available, including the Bureau of Labor Statistics, Law Enforcement Assistance Administration, National Center for Health Statistics, Social Security Administration, and Veterans' Administration.

SOCIAL AND ECONOMIC CHARACTERISTICS OF THE OLDER POPULATION: 1974

INTRODUCTION

This report brings together, in a single publication, a variety of social and economic characteristics of the older population. Many of these statistics have already been published in Census Bureau and other governmental publications and are now being brought together as a matter of convenience to the interested user, but some data are being presented here for the first time. The data in this report are primarily from the 1970 census and the March 1974 Current Population Survey. Below are presented a few summary statistics, which became available shortly before publication, based on the March 1975 Current Population Survey.

INTRODUCTION—Continued

2

For purposes of this report, the "older" population is defined as the population 65 years old and over. The lower climit has been arbitrarily placed at 65 years in recognition of a number of factors which, over the years, have combined to make the attainment of age 65 a milestone—for example, a time for retirement, Social Security benefits and Medicare coverage, income tax advantages, and reduction in transit fares and admission prices. This is also an age group which has come to be identified with low income, widowhood, and loneliness. In some tables, comparative statistics are shown for segments of the population below age 65 as well, particularly the 55 to 64 year olds. In a number of areas, especially those of an economic nature, there are dramatic differences between the age groups 55 to 64 and 65 and over. For many persons, the 10 years prior to their 65th birthday represent their peak years—or high plateau years—of earning power and of income per family member; in sharp contrast, this period is followed by the reduced income of their retirement years.

There are striking differences in a number of areas among segments of the elderly and between the elderly and the younger adult population. There are also similarities in some facets of their lifestyle. These similarities and differences are explored in relation to such characteristics as family and marital status, institutional population, nativity and parentage, mobility, residence, educational attainment, vocational training, voting rates, veteran status, labor force participation, occupation and industry, income and earnings, low-income status, housing, factors relating to health and to the utilization of health services, and crime victimization:

A CENTURY OF GROWTH

Since the turn of the century, the population 65 years old and over has increased at a rate more than twice that of the total-population. While the total population has roughly tripled from 76 million in 1900 to 212 million in 1974, the population 65 and over has increased from 3 million to 22 million. Persons 65 and over constituted about 4 percent of the 1900 population but now constitute 10 percent of the total population.

The female population 65 and over has grown even faster. Counts of men and women of this age were quite similar during the earlier censuses of this century, but women 65 and over now outnumber the men 12.8 million to 9.0 million.

The 65 and over segment of the population is expected to climb by the year 2000 to about 30.6 million persons, an increase of about 40 percent over the present number. It would then comprise, depending upon the level of future fertility, as much as one-eighth of the total population.

FAMILY, MARITAL STATUS, AND FERTILITY

Persons 65 years old and over tend to live with few other persons and with relatives only. In 1974, about 80 percent of all families with a head of this age consisted of two persons. Only about 2 percent of the households headed by a persons 65 or over included nonrelatives of the head. Women living alone or with nonrelatives only accounted for a significant portion—about one-third—of all household heads 65 years and over. This type of household was second in this age group to husband-wife households, which accounted for about 46 percent of all households headed by persons 65 or over.

Around one-sixth (18 percent) of the families in the Nation contain at least one member who is 65 years old and over, although family members at this age level accounted for only about 8 percent of all family members.

The proportion of men 65 years and over who were household heads increased from 87 percent in 1960 to 91 percent in 1970. Among women, the corresponding increase was from 38 percent to 45 percent. During the same period, the proportion of men who were the father or the father in law of the household head decreased from 7 percent to 4 percent, and the proportion of women who were the mother or the mother in law of the head decreased from 17 to 13 percent.

The most common marital status among men 65 and over is to be married, with a wife present. Because men are usually older than their wives and have higher mortality rates, widowhood is the most common state among women of this age group. In 1974, about 78 percent of white men 65 and over, and 60 percent of Negro men, were married with a wife present. Corresponding percentages of women with husband present were 38 and 26 percent. About half (52 percent) the white women and 64 percent of Negro women were widowed, compared with 14 percent of white men and 23 percent of Negro men.

As would be expected, the proportion of persons with their spouse present declines with increasing age while the proportion widowed increases. By age 85 and over, the proportion of men who are married is about the same as for those who are widowed, about 43 percent in 1970, whereas for women the discrepancy was considerable, 11 percent married compared with 77 percent widowed. For all ages 65 and over, the proportion of men who are single and who are divorced, however, are very similar to those for women. Overall, about 8 percent of men and women 65 and over had never married, and about 3 percent were divorced.

Education is related to marital status and to the factors affecting marital status. The proportion of men in 1970 who were married and with their wives present tended to increase with increased educational attainment and the proportion of those who were widowed tended to decrease. However, among men 65 years old and over, there was little difference in the percent who were single according to years of school completed.

Women 65 years old and over, unlike men, showed marked differences in the percent single between the lower and the higher levels of education. Among all women of these ages in 1970, about 8 percent were single compared with about 19 percent of those who had completed 4 years of college and about 36 percent of those who had completed 5 or more years of college. Although it is beyond the scope of this report, it would be interesting to know the extent to which these differences are attributable to such factors as: (a) the reluctance of some men to marry more highly educated women, (b) the rejection of marital opportunities by a woman while pursuing an education and then not finding acceptable opportunities later, or (c) a conscious choice on the part of a woman to prepare for a career without marriage.

White women, 65 years old and over, had borne fewer children on the average than had Negro women of the same ages, about 2.8 children for white women who were ever married compared with about 3.1 for Negro women, according to 1970 census data. Among both white and Negro women, those well above 65 years of age had borne more children on the average than had those just above 65 years, reflecting the higher fertility rates of the earlier cohorts.

INSTITUTIONAL POPULATION.

Approximately 1 million persons 65 years and over were living in institutions in 1970. About 8 out of 10 of these were in homes for the aged and another 1 out of 10 were in mental hospitals and residential treatment centers. The remainder were patients in hospitals because of physical reasons or were inmates of correctional and other institutions. About twice as many women as men were in institutions, reflecting their greater incidence in homes for the aged which is in harmony with their greater numbers mong the older population. (The institutional population was counted in the census but was excluded from the Current Population Survey. Similarly, all members of the Armed Forces were included in the census, but in CPS only those members of the Armed Forces in the United States living off post or living with their families on post were included.)

11

NATIVITY AND PARENTAGE

Persons 65 years and over comprise a larger share—about one in every five overall—of the foreign stock population (the foreign born plus native persons of foreign or mixed parentage) than of the total population (1 in every 10). One-third of the foreign-born population and one-sixth of native persons of foreign or mixed parentage were 65 years and older.

For the 33.6 million population of foreign stock (of all ages) in 1970, the leading countries of origin were Italy, Germany, and Canada. There was wide variation by country in the age distribution of persons who were foreign stock. There were some countries of origin, for example, from which as many as 1 of every 3 persons of foreign stock was 65 years or over—Denmark, Germany, Ireland, Norway, and Sweden—and others from which less than 1 in 10 was 65 and over—Cuba, China, Japan, and Mexico. These differences reflect in large part the periods during which immigrants from various countries entered the United States, with the latter groups representing immigration of a more recent period.

14

MOBILITY AND RESIDENCE -

Persons 65 and over change residence infrequently—at less than half the rate of the total population. About four out of five persons (79 percent) 65 and over lived in the same house in 1974 as they did in 1970. Even so, 3.5 million persons 65 and over moved during the 4-year period; many of those who moved (60 percent) remained within the same county.

About two out of three persons 65 and over lived in metropolitan areas in 1970, and about half-of these lived in the central cities. In nonmetropolitan areas, a small percentage lived on farms, whereas the bulk of the residents were about equally divided between urban and rural nonfarm areas.

EDUCATION, VOCATIONAL TRAINING, AND LITERACY

The recent strides in education which are so clearly evident in the younger population are also manifested in the population 65 and over, although for the most part that segment of the population completed their education prior to 1935. About 33 percent of the white men 65 and over had at least a high school education in 1974, compared with 26 percent for this age group in 1970 and 18 percent in 1960, reflecting increased educational attainment levels of younger cohorts. Among white women, 36 percent had completed at least 4 years of high school in 1974, compared with 31 percent in 1970 and 22 percent in 1960. Data for Negre men and women in this age group appear to show similar trends but their numbers are too small to detect statistical significance in their apparent differences,

In 1970, about 21 percent of men 65 and over and 18 percent of women of the same ages had completed some type of vocational training program. Among both men and women, the proportion completing a vocational program tended to be higher as education increased but dropped off slightly among college graduates. About 18 percent of the men with less than a high school education had completed a program, compared with about 31 percent of high school graduates who had not gone on to college. About 26 percent of male college graduates had completed a vocational training program.

Among women 65 and over, about 13 percent of those with less than a high school education had completed a vocational training program; corresponding percentages for high school graduates and college graduates were 29 percent and 24 percent, respectively.

The most recent survey on literacy (1969) indicated that about 650,000 persons or 19 percent of the 3.5 million persons 65 and over with less than a sixth grade education were illiterate, that is, they could not read and write in any language. (This survey, by definition, included in the literate category all persons having a sixth grade education or more.) Women were somewhat more likely to be illiterate than men (21 percent compared with 16 percent), and Negroes 65 and over were about twice as likely to be illiterate as white older persons (31 percent compared with 15 percent). About one-half of the 1 million persons who had completed less than 2 years of school were illiterate compared with about 20 percent of those who completed 2 years of school and 8 percent of those who completed 3 years of school.

VOTING

About three out of every four persons 65 years old and over reported that they were registered to vote in the 1972 Presidential election. About five out of every six of those who were registered reported that they had voted. Higher percentages of persons aged 65 to 74 voted than did those 75 years and over (68 percent compared with 56 percent); higher percentages of men than women.65 and over voted (71 percent compared with 58 percent); and higher percentages of white persons than Negroes of this age voted (65 percent compared with 51 percent).

In the 1974 Congressional election, about 70 percent of persons 65 and over were reported registered as against 76 percent in the Presidential election of 1972, and just about half (51 percent) reported voting in 1974 compared with 64 percent in 1972. (Voter turnout is usually smaller in non-Presidential election years.) Still, persons 65 and over were more likely to register than the total population (62 percent) and, having registered, were also more likely to vote (51 percent versus 45 percent).

VETĒRANS

In 1970, approximately 2.2 million men 65 years old and over were veterans, roughly one-fourth of all males 65 and over. About 9 out of 10 of these veterans were in service while this country was at war. The great majority of these served during World War I, with a significant number serving during World War II.

In June 1974, of the 2.2 million veterans receiving compensation from the Veterans Administration for service-connected disabilities, 193,000, or 9 percent, were 65 and over. In addition, 60 percent of the 1 million veterans receiving pensions for nonservice-connected disabilities were 65 and over. Thus, better than one out of every three veterans 65 and over were receiving some form of veterans' disability pension.

The 155,000 hospitalized veterans 65 and over accounted for 15 percent of the 1 million total veterans hospitalized during the fiscal year ending June 1974.

LABOR FORCE PARTICIPATION, EMPLOYMENT STATUS, AND OCCUPATION AND INDUSTRY

Since 1940, there has been an overall decline in the labor force participation rate of persons 65 years and over, but that decline has not held for both sexes. Among men of this age group, 42 percent were in the labor force in 1940 but only 22 percent in 1974, reflecting the tendency toward earlier retirement in recent years. Women, on the other hand, showed some tendency toward an increase between 1940 and 1970, from 6 percent to 10 percent, but since then they, too, have shown signs of a decrease in labor force participation, down to 8 percent in 1974.

Differences by race in worker level among the elderly have greatly decreased—from 8 percentage points in 1940 to 1 percentage point in 1974. In 1940, about 23 percent of white persons 65 and over were in the labor force-compared with 31 percent of persons of Negro and other races. In 1974, around 14 percent of the elderly were in the labor force.

About 2.0 million men and 1.1 million women 65 years old and over were employed in 1970. More than half of these employed men and women (about 58 percent of each) were between the ages of 65 and 69. Around one percent of all men and 27 percent of all women 65 and over had neve worked.

Persons 65 and over with few years of school completed tend to have lower rates of participation in the labor force than do persons who have completed more years of schooling. For example, among males 65 and over, in , 1974, only about 12 percent of those who had completed less than 5 years of school were in the labor force, compared with 25 percent of high school graduates with no additional education and 48 percent of those with 5 years or more of college. This phenomenon could be the consequence of several factors, such as more highly educated persons being in more personally satisfying and better paying positions which they are reluctant to leave; being in positions in which their skills are in relatively short supply and their employer is reluctant to release them; and being self-employed in greater proportions and thus not subject to arbitrary retirement ages.

Among women, higher rates of participation were also experienced at the higher than at the lower education levels but the rates were lower than for men with corresponding education.

In 1974, there was a marked difference in labor force participation rates for persons in the 10-year period just before the popular retirement age of 65 compared with those at and just beyond this age. Among men, about 79 percent of those 55 to 64 years, and 34 percent of those 65 to 69 years, were in the labor force. About 42 percent of women 55 to 64, compared with 14 percent of those 65 to 69, were in the labor force.

There is some suggestion from the figures that many women 65 and over who have left the labor force by way of retirement may report "keeping house" as their major reason for not being in the labor force, whereas men may tend to report "retired" even if they are doing their own housekeeping.

Annual average figures for 1973 from the Bureau of Labor Statistics show that more men 65 and over were in white-collar occupations (42 percent) than in any other of the four major occupation classes. About 27 percent were blue-collar workers, 18 percent were in farm occupations, and 13 percent in service occupations. The proportion of men employed in white-collar occupations was about the same for those 65 to 69 and for those 70 years and over. A similar age pattern was found for service workers. A somewhat higher percentage of men 70 years and over, however, were farm workers than were men in the 65 to 69 group, about 21 percent compared with 16 percent. However, there was a lower percentage of blue-collar workers among those 70 years and over than among those 65 to 69 years.

Women 65 and over were also more likely to be employed in white-collar occupations (52 percent) than in any other group, with service occupations second (about 34 percent). Within the white-collar group, however, men were primarily managers and administrators, whereas women were primarily in clerical positions.

LABOR FORCE PARTICIPATION, EMPLOYMENT STATUS, AND OCCUPATION AND INDUSTRY—Continued

There were also variations by age within the major occupation groups for persons 65 years and over and those 55 to 64 years. A considerably larger proportion of men 55 to 64 years old than of those 65 years old and over were in blue-collar occupations, 44 percent compared with 27 percent. Among women, 34 percent of those 65 years and over were in service occupations, but only 25 percent of those 55 to 64 years were in these occupations.

Men 65 and over, more so than those 55 to 64 years, were employed in agricultural industries in 1974. About 20 percent of those 65 and over, compared with 8 percent of those 55 to 64 years, were in agricultural industries.

Within the nonagricultural industries, both men and women in the 65 and over group were more likely to be self-employed than those 55 to 64, about 19 percent compared with 11 percent for men and 14 percent compared with 6 percent for women. Women 65 and over were more likely than those 55 to 64 to be employed as private, household workers, 15 percent to 7 percent, but less likely to be government employees, 13 percent to 21 percent.

Among employed men 65 and over in 1970, there was no clearly dominant industry. In the male work force among the 45 to 64 age group, manufacturing was the front-runner, accounting for around 30 percent of the employed.

Among employed women, industries in the field of professional and related services (including school teaching and hospital nursing care) led with about 29 percent, a level which was maintained in both the 65 and over group and the 45 to 64 group.

In 1970, about 1.2 million working men and 700,000 working women 65 years old or over—approximately 58 percent of the work force in this age group—lived in SMSA's having a population of 100,000 or more. Their means of transportation to work is of particular interest during this period of energy conservation awareness. A majority of these men, about 60 percent, drove to work in private automobiles. Although one-third of the women also drove to work, about one-half of them used either public transportation or some means other than as a driver or passenger of a private tomobile. (Among all workers 16 and over in these SMSA's, about 74 percent of the males and 54 percent of the females drove to work.) Both men and women 65 and over who lived inside a central city and worked in the central business district relied on public transportation to travel to work much more so than did persons of the same sex who lived inside a central city but worked outside the central business district. (Table 24)

Table 23. LABOR FORCE STATUS OF PERSONS 65 YEARS OLD AND OVER. BY RACE AND SEX: 1940 TO 1974

Sumbors in thousands. For years prior to 1980, excluded data for Alaska and Hawaii. All years except 1974 based on sample from decennial consumes; 1974 based on Current Population Survey. 1970 statistics based on 20-percent sample, 1980 statistics on 25-percent sample, 1980 statistics on 3-1/3-percent sample, and 1940 statistics on 5-percent sample.

INCOME AND EARNINGS

Men. 65 years and over with an income had a 1973 median income of \$4,100 compared with about \$9,600 for men. 55 to 64 years, a contrast reflecting the higher proportion of retirees within the older group. Similarly, women. 65 and over had a lower median income than women 55 to 64 years, and in each of these age groups the median income for women was considerably lower than for men of the same ages. The median income of women 65 and over was \$2,100; it was \$3,400 for women 55 to 64 years.

Single, widowed, or divorced persons 62 years old or older who lived in families had a lower median income than those who did not, about \$2,100 compared with \$2,800. Those who were more capable of self-maintenance tended to live apart from relatives.

Families with heads 55 to 64 years old had a 1973 median income approximately double that of families with heads 65 years old or over, about \$13,400 compared with \$6,500. Although families with a female head 55 to 64 also had income in excess of those with a head 65 and over, the difference was not as pronounced, about \$7,900 compared with \$6,100.

Families headed by a woman 65 or over had a median income about the same (around \$6,000) as those headed by a man of that age in which the wife was not in the paid labor force. This was not the case, however, in families with a head 55 to 64 years. Among these families, those headed by a woman had a median income of about \$7,900 while those headed by a man whose wife was not in the paid labor force had an appreciably higher median income of about \$12,000.

The median family income of families containing men 65 years old and over is considerably lower (\$6,600) than for families with men 62 to 64 years (\$11,100) or 55 to 61 (\$14,200). Within the families which include a man 65 years old or over, the median family income is about twice as high if the man is related to the head as it is if he is the head. Presumably this is a reflection of the higher, active labor force income of a generally younger family head in the first case and the lower, largely retirement income of the 65 and over head in the second case. This kind of difference does not occur in families having men 55 to 61 and 62 to 64 years old, in which the men are normally still in the labor force.

Of special interest is the fact that among families with a head 65 years old or over those headed by a female had a 1969 median income somewhat higher than that for husband-wife families. (Table 36)

Unrelated individuals 65 years old and over had a 1969 median income of about \$1,800. These persons live alone or with persons to whom they are not related. About 3 out of 4 (75 percent) of these persons had no income from earnings but were primarily dependent on Social Security income, either exclusively or in combination with sources of income other than earnings. Around 5 percent had only earnings with no other source of income.

NOTE: The income shown in the two sections on income ("Income and Earnings" and "Low-income Persons and Families") relates to income for the previous calendar year, while the statistics on the number and characteristics of persons and families relate to those persons or families as of the sample survey or census date. Thus, for a Current Population Survey table showing 1973 income, the income was accumulated in 1973 but the survey date was March, 1974. Similarly, 1970 census income data relate to income received in 1969 although the official census date was April, 1970.

LOW-INCOME STATUS OF PERSONS AND FAMILIES

Approximately one in every six persons 65 years old or over (16 percent) was below the low-income level in 1973. Smaller percentages of persons 55 to 64 than of those 65 and over were below the low-income level. Women 65 and over were more likely than men to be below this level, about 19 percent compared with 12 percent. Similarly, older persons living in nonmetropolitan areas were more likely than metropolitan residents to be below the low-income level, 23 percent versus at a percent.

Among Negroes, three out of every eight persons 65 and over (37 percent) were below the low-income level. Half of all Negroes 65 and over living in nonmetropolitan areas and a fourth of all Negroes in metropolitan areas were below the low-income level.

Some 829,000 families with the head 65 or over, or 11 percent of all families with a head of this age, were below the low-income level in 1973. Families headed by a woman in this age group were more likely to be below the low-income level than those headed by a man of similar age. About 9 percent of these families with a male head, but 17 percent with a female head, were in this category. Interestingly, families headed by relatively young women are below the low-income level in greater proportions than are those headed by women 65 years or over. About 32 percent of all families headed by a woman were low-income families compared with the 17 percent for families headed by a woman 65 or over. The relationship was similar for white and Negro women. Among white families headed by a woman, about 10 percent of those with a head 65 or over were below the low-income level and about 25 percent of all families; among Negro families headed by a woman, about 44 percent of those headed by a woman 65 or over, compared with 53 percent of all Negro families with a female head, were below the low-income level.

In about every category of families and unrelated individuals, Negroes were more likely—and sometimes considerably so—to be below the low-income level than the total population.

As might be expected, the higher the level of education of the family head 65 and over, the smaller the percentage of such families below the low-income level. In families headed by a person 65 and over, about 19 percent of families in which the head had less than an eighth grade education were below the low-income level, 9 percent of those in which the head had an eighth grade education, and 3 percent of those in which the head was a college graduate.

HOUSING

Household heads 65 and over hold their own in home ownership compared with the total population. In 1970, 63 percent of all households, and 68 percent of those with a head 65 and over, were owner occupied.

An overwhelming proportion (around 70 percent) of the owner-occupied units with a head of household 65 and over had been built prior to 1950 with more than half having been built before 1940. Similarly, a substantial portion of these units had been occupied by the current owners for more than 20 years. Greater percentages of heads 75 and over than of those 65 to 74 in the corresponding type of household were living in structures built before 1940 and had moved into their units before 1950.

Renter-occupied households headed by persons 65 years old or over were more likely to contain a person living alone than to contain two or more persons. About 2.3 million households headed by a renter 65 or over were occupied by the head only, compared with about 1.7 million which were occupied by at least one other person, usually the spouse.

Somewhat greater percentages of the two-or-more person households were in single-unit structures than was true of one-person households. Conversely, one-person households were more likely than larger households to be located in structures having 20 or more units.

Regardless of household composition, more than half of these renters lived in structures built prior to 1940; however, they were about as likely to have moved into their unit during the preceding 5 years as to have moved there earlier. The one-person households were more likely to consist of three rooms and the other households of four rooms than of any other size unit.

Households in which the head and wife were both present were more likely than other households to consist of exactly two persons. In households of two or more persons headed by a 65 to 74 year old, about 78 percent of the husband-wife households contained two persons compared with about 71 percent of households with a female head. In similar households with the head 75 years old or older, about 85 percent of the husband-wife households contained two persons, compared with 67 percent of households headed by a male with no wife present and 76 percent of those headed by a female.

HEALTH AND HEALTH SERVICES

Persons 65 years old and over are less likely than the total population to suffer an injury but are considerably more likely to have a limitation of activity because of a health or physical condition. They also have a higher average number of restricted activity days and more days of bed disability. In 1972, about 43 percent of the population 65 and over had an activity limitation, compared with 13 percent of the total population. However, 31 percent of the total population, compared with 21 percent of persons 65 years and over, were injured during the year.

Among persons 60 to 64 years old, about one person in four was reported in the 1970 census to have some type of work disability. Of those who were disabled, more than half, 57 percent, had a complete work disability. About 31 percent of all persons of this age with a work disability had been completely disabled for 5 years or more. Another 22 percent had been partially disabled for that length of time.

Among those 65 and over, the disabled women were more likely than their male counterparts to have had a complete work disability, about 65 percent compared with 49 percent, and to have had the disability for 5 years or more, about 39 percent compared with 23 percent. Similarly, Negroes who were disabled were more likely than white persons to have a complete work disability (about 65 percent compared with 56 percent) and to have endured that disability for a period of 5 years or more (about 37 percent compared with 30 percent).

During 1972, about 3.5 million persons 65 and over had some type of mobility limitation because of a chronic condition. About three out of every 10 of these persons had a limitation sufficiently severe to keep them confined to the house, and the remainder, though able to leave the house, needed the assistance of another person or aid such as a wheelchair.

Persons 65 and over experienced an average of about 9 days of restricted activity each quarter in 1972. On the average, they stayed in bed 3 or 4 days during the quarter and missed a day of work because of disability.

On the average, two out of every three persons 65 and over had visited a physician during the previous 6 months and one out of five had visited a dentist. This population group made an average of about 14 visits to a physician and one visit to a dentist during the year. About 7 percent had not visited a physician, and about half of the population 65 and over had not visited a dentist, in at least 5 years. (About 51 percent of all persons 65 years old and over were edentulous in 1971, that is, they had no teeth.)

Although the number of persons using services covered by Medicare during the 5 years from 1967 through 1971 increased each year, the total number of persons enrolled also increased at about the same rate so that a constant share of enrollees, about 79 percent, used covered services. Each year during this period about 75 percent of enrolled men 65 and over and around 80 percent of enrolled women used covered services. The average charge for covered services per person was around \$150 in 1967 and in the area of \$200 in 1970 and 1971.

By far, the major cause of death in 1972 of persons 65 years and over was heart disease. Among the 10 leading causes, diseases of the heart accounted for as many deaths as did the remaining nine causes combined. The second leading cause was malignant neoplasms, followed by cerebrovascular disease. Accidents rated sixth.

50

CRIME VICTIMIZATION

The population 65 and over suffered about one-fourth as many crimes, relatively, against their person during the first half of 1973 as did the population 12 years old and over, about 15 crimes per 1,000 population compared with 64 per 1,000. For each of the two age groups, larceny was by far the most frequent crime (about 70 percent) followed by assault.

In crimes against households, those households headed by a person 65 years and over were victimized to a lesser extent than all households for each of the three household crimes considered. Motor vehicle theft accounted for a relatively minor portion of household crimes, but burglary and household larceny accounted for the great majority of cases.

Criminal Victimization in the United States; Volume I.

SOURCE AND RELIABILITY OF THE ESTIMATES

Source of Data. Most of the estimates in this report are based on data from the Current Population Survey of the Bureau of the Census and from the Decennial Censuses of Population and Housing, particularly the 1970 census. Other data were provided by various governmental agencies which include the Bureau of Labor Statistics; Department of Health, Education, and Welfare; Veterans Administration; and the Department of

Justice. Brief descriptions of the sources and/or the procedures by which the data were obtained are presented below.

Current Population Survey (CPS). The following table provides a description of some aspects of the Current Population Survey design.

DESCRIPTION OF THE CURRENT POPULATION SURVEY

	Number of		Households	Households	
Time period	sample areas	Number of counties ¹	Inter- viewed	Not inter- viewed	visited, not interviewed ²
1972 to present	461 449 449 357	923 863 863 701	45,000 45,000 48,000 33,500	2,000 2,000 2,000 1,500	8,500

 $^{^{1}}$ These are the number of counties and independent cities with coverage in each of the 50 States and the District of Columbia.

The estimating procedure used in the Current Population Survey involves the inflation of the weighted sample results to independent estimates of the civilian noninstitutional population of the United States by age, race, and sex. These independent estimates are based on statistics from the previous Decennial Census of Population, statistics of births, deaths, immigration and emigration, and statistics on the strength of the Armed Forces. Some of the CPS estimates for this report have already been published in the P-20 and P-60 series of CPS derived data.

Decennial Census of Population. Decennial census data in the report are based on complete counts or on the samples associated with the census. All data in this report from the 1950 or earlier decennial censuses are based on complete counts. Descriptions of the 5-, 15-, and 20-percent samples from the 1970 census are found in the appropriate census publications. The 1970 Decennial Census tables appear in three special series of volumes: two for Population counts—PC(1) and PC(2) and one for Housing counts—HC7. Additionally, 1970 census data appear in U.S. Summary volumes.

Veterans Administration Data. The data of table 22 were obtained by the Veterans Administration from administrative records.

Current Medicare Survey (CMS). Data collected from the Current Medicare Survey (CMS) for this report (data from 1967 through 1971) are based on a sample which was spread over 105 areas with coverage in each of the 50 States and the District of Columbia. The CMS was a sample or those persons who received either or both parts of Medicare benefits. The sample persons were selected directly from the Medicare rolls for each sample PSU. The full sample, which was interviewed monthly for each of 15 consecutive months, consisted of about 5,200 persons. For about 2 percent of the persons visited, on the average, interviews were not obtained.

²These are households which were visited, but were found to be vacant or otherwise not to be interviewed.

 $^{^{1}\}mbox{Medicare}$ has two parts: (1) hospital benefits and (2) supplemental benefits.

Health Interview Survey (HIS). Data collected from the Health Interview Survey in 1972 are based on a sample spread over 357 areas with coverage in each of the 50 States and the District of Columbia. The HIS sample of 1972 consisted of approximately 57,000 assigned households, of which 11,000 were vacant, demolished, or occupied by persons not in the scope of the survey. The 46,000 eligible occupied households in 1972 yielded a probability sample of about 134,000 persons in 44,000 interviewed households.

Vital Statistics Data. Data on mortality rates are published by the Office of Health Statistics Analysis of the National Center for Health Statistics, Department of Health, Education, and Welfare. The children ever born statistics of table 10 are based on 1970 census data.

Crime Data. The data on crime are published by the Law Enforcement Assistance Administration and were obtained from the National Crime Survey. The National Crime Survey is based on data obtained from a stratified multi-stage cluster sample from 376 strata, and is 2. conducted on a quarterly basis to produce quarterly estimates and rates of crime victimizations. Approximately 75,000 housing units and other living quarters are designated for the sample. Of these, about 12,500 units are found to be vacant, demolished, converted to nonresidential use, or ineligible for some other reason. An additional 2,500 households are not interviewed because no one is at home after repeated visits by the interviewer, the residents refuse to be interviewed, are temporarily absent, or are unavailable for some other reason.

Reliability of the Estimates. Since many of the estimates are based on a sample, they may differ somewhat from the figures that would have been obtained if a complete census had been taken using the same schedules, instructions, and enumerators. As in any survey work, the results are subject to errors of response and of reporting as well as being subject to sampling variability.

The reliability of an estimate is described in terms of standard errors which are primarily measures of sampling variability, that is, of the variations that occur by chance because a sample rather than the whole of the population is surveyed. As calculated for this report, the standard error also partially measures the effect of certain response and enumeration errors, but it does not measure, as such, any systematic biases in the data. The chances are about 68 out of 100 that an estimate from the sample would differ from a complete census figure by less than the standard error. The chances are about 90 out of 100 that this difference would be less than 1.6 times the standard error, and the chances are about 95 out of 100 that the difference would be less than twice the standard error.

All statements of comparison appearing in the text are significant at a 1.6 standard error level or better, and most are significant at a level of more than 2.0 standard errors. This means that for most differences cited in the text, the estimated difference is greater than twice the standard error of the difference. Statements of comparison qualified in some way (e.g., by the use of the phrase "some evidence") have a level of significance between 1.6 and 2.0 standard errors.

The figures presented in all the standard error tables are approximations to the standard errors of various estimates shown in this report. In order to derive standard errors that would be applicable to a wide variety of items (for a given subject matter) and could be prepared at a moderate cost, a number of approximations were required. As a result, the tables of standard errors provided are an indication of the order of magnitude of the standard errors for a given subject matter rather than the precise standard error for/any specific item.

The reliability of an estimated percentage, computed by using sample data for both numerator and denominator, depends upon both the size of the percentage and the size of the total upon which the percentage is based. Estimated percentages are relatively more reliable than the corresponding estimates of the numerators of the percentages, particularly if the percentages are 50 percent or more

Comparability with other data. Data obtained from the Current Population Surveys and other governmental sources are not entirely comparable. This is due in large part to differences in interviewer training and experience and in the differing survey processes. This is an additional component of error not reflected in the standard error tables. Therefore, caution should be used in comparing results between these different sources.

Data based on the CPS sample. Tables of standard errors for estimates and percentages for characteristics pertaining to the total or white population (tables A-1 and A 3) and to Negro and other races (tables A 2 and A-4) are presented below. When two or more characteristics have nearly equal standard errors (e.g., total population and white population), only one table is presented to represent them. Table A-5 represents factors which are to be applied to the figures in tables A-1, A 2, A 3 and A 4 to produce standard errors for the various subject matter areas. For example, to produce approximate standard errors for estimates of total persons or white persons in low income categories based on data collected in the CPS after January 1967, multiply the appropriate figures in tables A-1 or A-3 by the factor 1.7. The factors for families and households should be used for items which can typically appear only once in a given household, e.g., "Number of household heads."

Table A-1. STANDARD ERRORS OF ESTIMATED NUMBERS, TOTAL OR WHITE POPULATION

CPS Estimates

(In thousands, 68 chances out of 100)

Size of estimate	Standard error	Size of estimate	Standard error
			τ.
100	14	5,000	88
250	23	7,500	. 90
500	32	10,000	103
1,000,	44	12,500	101

3,000	73	17,500	74
4,000	82	20,000	36

Note: For a particular characteristic, see table A-5 for the appropriate factor to apply to the above standard errors.

Table A-2. STANDARD ERRORS OF ESTIMATED NUMBERS, NEGRO AND OTHER RACES

CPS Estimates

(In thousands. 68 chances out of 100)

Size of estimate	Standard error	Size of estimate	Standard error	
75 100 200 300 400	14 16 22 26 30 32	750 1,000 1,250 1,500	35 36 34 28 11	

Note: For a particular characteristic, see table A-5 for the appropriate factor to apply to the above standard errors.

Illustration of the use of tables of standard errors. Table 19 of this report shows that in November 1972 there were 11,726,000 females of all races 65 years old and over in the United States. Table A-1 shows the standard error of an estimate of this size to be approximately 101,600 by use of linear interpolation. The factor in table A-5 for voting for the total or the white population is 1.1; thus the resulting standard error is approximately 112,000 (101,600 x 1.1). The chances are 68 out of 100 that the estimate would have been a figure differing from a complete census figure by less than 112,000. The chances are 95 out of 100 that the estimate would have been a figure differing from a complete census figure by less than 224,000 (twice the standard error).

Table 19 also shows that of the 2,878,000 males 75 and over of all races, 14.1 percent reported they were registered to vote and also reported that they did not vote. Table A-3 shows the standard error of 14.1 percent on a base of 2,878,000 to be approximately 0.9 percentage points. The factor from table A-5 for this characteristic is again 1.1. Applying the factor 1.1 to the standard error obtained from table A-3 for 14.1 percent provides an approximation of the standard error to be about 1.0 percentage points. Consequently, chances are 68 out of 100 that the estimated 14.1 percent would be within 1.0 percentage points of a complete census figure, and chances are 95 out of 100 that the estimate would be within 2.0 (2 x 1.0) percentage points of a complete census figure, i.e., this 95 percent confidence interval would be from 12.1 to 16.1 percent.

Standard error of a difference. For a difference between two sample estimates, the standard error is approximately equal to the square root of the sum of the squares of the standard error of each estimate considered separately. This formula will represent the actual standard error quite accurately for the difference between two estimates of the same characteristic in two different areas, or for the difference between separate and uncorrelated characteristics in the same area. If, however, there is a high positive correlation between the two characteristics, the formula will overestimate the true standard error.

Illustration of the computation of the standard error of a difference. Table 19 of this report shows that of the 5,470,000 males 65 to 74 years old of all races in November 1972, 9.7 percent reported they were registered but did not vote. Thus, the apparent difference between the percent of males of all races who were 65 to 74 who were registered to vote, but did not, and the percent of males 75 and over who were registered to vote, but did not, is 4.4 percent (14.1 - 9.7). The standard error of 14.1 percent is 1.0 percent as shown above. Table A-3 shows the standard error of an estimate of 9.7 percent for a base of 5,470,000 persons to be approximately 0.6 percentage points. Again, table A 5 shows a factor of 1.1 for voting for persons of all races. Applying this factor to the standard error obtained from table A-3 provides an approximation to the standard error of 0.7 percentage points. The standard error of the estimated difference of 4.4 percent is

1.2 percent = $\sqrt{(.7)^2 + (1.0)^2}$. This means the chances are 68 out of 100 that the estimated difference based on the sample would differ from the change derived using complete census figures by less than 1.2 percentage points. The 68 percent confidence interval around the 4.4 percent difference is from 3.2 to 5.6 percent, i.e., 4.4% \pm 1.2%. A conclusion that the average estimate of the difference derived from all possible samples of the same size and design lies within a range computed in this way would be correct for roughly 68 percent of all possible samples. The 95 percent confidence interval is 2.0 to 6.8 or 4.4 \pm 2(1.2). Since the 95

percent confidence interval does not contain the number zero, we can conclude with 95 percent confidence that the oroportion of males 65 to 74 is different than the proportion of males 75 and over for the category of these persons who reported they had registered to vote and reported that they did not vote.

Standard error of a median. The sampling variability of an estimated median depends upon the form as well as on the size of the distribution from which the median is determined. An approximate method for measuring the reliability of a median is to determine an interval about the estimated median, such that there is a stated

Table A-3. STANDARD ERRORS OF ESTIMATED PERCENTAGES, TOTAL OR WHITE POPULATION

CPS Estimates

¹For the low-income data from 1966 of table 38, additionally multiply by the factor 1.2. For the data in table 39 which is broken down by Metropolitan or Nonmetropolitan residence, additionally multiply by the factor 1.4.

degree of confidence that the median based on a complete census lies within the interval. The following procedure may be used to estimate confidence limits of a median based on sample data: (1) From tables A-3 and A-4 and the factor table A-5, determine the standard error of a 50 percent characteristic using the appropriate base; (2) add to and subtract from 50 percent the standard error determined in step (1); and (3) using the distribution of the characteristic, read off the confidence interval corresponding to the two points established in step (2). A two-standard error confidence interval may be determined by finding the values corresponding to the 50 percent plus and minus twice the standard error determined in step (1).

Illustration of the computation of a confidence interval for a median. Table 26 shows that the median number of years of education for males 65 years old and over who were not in the labor force in March 1972 was 8.6. The size, or base, of the distribution from which this median was determined is 6,233,000 persons.

- 1. Table A 3 shows that the standard error of 50 percent on a base of 6,233,000 is about 0.9 percent. Applying the appropriate factor from table A-5, the standard error of 50 percent for an Employment or Non Labor Force, Total or White, Male Only, characteristic is $0.9 \times 0.7 = 0.6$ percent.
- 2. To obtain a two-standard error confidence interval on the estimated median, initially add to and subtract from 50 percent twice the standard error found in step 1. This yields percentage limits of 48.8 and 51.2.
- 3. From table 26 it can be seen that 46.9 percent (956,300) had about 8 years of education and 14.2 percent (289,500) had more than 8 and less than 11 years of education. By linear interpolation the lower limit on the estimate is found to be about

$$8 + (3) \left(\frac{48.8 \cdot 46.9}{14.2} \right) = 8.4$$

Similarly, the upper limit may be found by linear interpolation to be about

$$8 + (3)\left(\frac{51.2 \cdot 46.9}{14.2}\right) = 8.9$$

Thus, the 95 percent confidence interval around 8.6 ranges from 8.4 to 8.9.

Treatment of Nonresponse in Mobility. For about five percent of the persons for whom information was obtained in March 1974, the interviewer was unable to obtain information about residence in 1970. The usual procedure for treatment of nonresponse is to create data

by an imputation procedure based on known population characteristics. However, no attempt was made to adjust for nonresponse for mobility and nonmobility. Table 14 reflects this nonresponse by having percentages of movers and nonmovers add up to only about 95, rather than 100, percent. As a consequence, the estimates for percentages of movers and of nonmovers should both be higher by some portion of the approximate five percent. It is unknown, however, how the five percent nonrespondents to residence in 1970 are distributed in regard to mobility.

RELIABILITY OF NON-CPS DATA

Data based on samples from the 1970 Decennial Census. Standard errors of all data, except for fertility rates, from the 5-percent sample of the decennial census shown in this report, are small enough to be disregarded. The standard errors may be found in the appropriate census volumes, PC(1), PC(2) of HC(7). Table A-6 of this report contains standard errors of 1970-based fertility rates.

Illustration of the use of the fertility standard error table. Table 10 of this report shows that in 1970 there were 837,000 black women ever married who were 65 years old and over. These women averaged 3,137 children per thousand women. Table A-6 shows the standard error of 3,137 children on a base of 837,000 women to be approximately five children. This means the chances are 68 out of 100 that the estimate would have shown a fertility rate differing from a complete census figure by less than five. The chances are 95 out of 100 that the estimate would have shown a fertility rate differing from a complete census figure by less than 10 (twice the standard error); i.e., the 95 percent confidence interval would be from 3,127 to 3,147 children ever born per thousand married black women 65 years old and over.

Data based on Vital Statistics. Since sample statistics are not involved in the numerator or denominator of any vital rate (mortality or fertility), the standard errors for such rates are zero.

Data based on the Health Interview Survey: United States - 1972. Standard errors for data tables 46, 48, 49 and 50 of this report can be obtained in the publication from which these data have been extracted. This publication is Vital Health Statistics, Series 10- Number 85, produced by the U.S. Department of Health, Education, and Welfare.

Data based on the Current Medicare Survey. Standard errors for data table 51 of this report may be found in the Current Medicare Survey Report, Supplementary Medical Insurance, First Quarter 1971 - CMS 20.

Crime Data. Tables A-7 and A-8 contain standard errors for the crime data of data tables 53 and 54, respectively, of this report.
